

Data driven style, Setup, Teardown and Resources

In this exercise you need to divide your exercise2 into a test case file with tags and a resource file. Test cases are to be defined in data-driven style, and the test data is read from a CSV-file.

What you need to do:

- Move all keyword definitions except the template keyword to a resource file.
- Add suite setup that:
 - Connects to Fluke as described in Exercise2
- Add suite teardown that:
 - Sets the device to local mode.
- Add test setup that:
 - Sets the device to remote mode
- Add test teardown that:
 - Turns off the ECG-signal
- Add a combination of tests with:
 - Four different heart rates
 - Four different body temperatures
 - Four different standard deviations
 - Adult and child
- All together you need to have 128 different test cases
 - There should be one second delay at the end of the test to simulate the time it takes to verify the results.
 - Test cases must be tagged with:
 - Adult/child
 - Low/high heart rate (under/over 100bpm)

Hint: write a Python program to generate the CSV-file.

Show to the instructor how the tests work on your computer and:

- Your test case file
- Your resource file
- CSV-file that contains the test data
- **A script** (shell script, bat, cmd, ...) that contains command lines to run the following tests:
 - All tests
 - All test in random order
 - All test and produce a filtered report of low heart rates
